1. Wireless Sensor Network Overview

The LORD MicroStrain® Wireless Sensor Network is a high-speed, scalable, sensor data acquisition and sensor networking system. Each system consists of wireless sensor interface nodes, a data collection gateway, and full-featured user software platforms based on the LORD MicroStrain® Lossless Extended Range Synchronized (LXRS®) data communications protocol. Bidirectional wireless communication between the node and gateway enables sensor data collection and configuration from up to two kilometers away. Gateways can be connected locally to a host computer or remotely via local and mobile networks. Some gateways also feature analog outputs for porting sensor data directly to standalone data acquisition equipment.

The selection of available nodes allows interface with many types of sensors, including accelerometers, strain gauges, pressure transducers, load cells, torque and vibration sensors, magnetometers, 4 to 20mA sensors, thermocouples, RTD sensors, soil moisture and humidity sensors, inclinometers, and orientation and displacement sensors. Some nodes come with integrated sensing devices such as accelerometers. System sampling capabilities are IEEE 802.15.4-compliant and include lossless synchronized sampling, continuous and burst sampling, and data logging. A single gateway can coordinate many nodes of any type, and multiple gateways can be managed from one computer with the Node Commander® and SensorCloud™ software platforms. Integration to customer systems can be accomplished using OEM versions of the sensor nodes and leveraging the LORD MicroStrain® data communications protocol.

Common wireless applications of the LORD MicroStrain® Sensing Systems are strain sensor measurement, accelerometer platforms, vibration monitoring, energy monitoring, environmental monitoring, and temperature monitoring.
2. Node Overview

The SG-Link®-LXRS® wireless sensor node features two analog input channels designed to accommodate a wide range of Wheatstone bridge and analog sensors including, strain, load cell, torque, pressure, acceleration, vibration, magnetic field, displacement, geophones, and more. There is one channel for single ended sensor measurement, one channel for differential sensor measurement, and an on-board internal temperature sensor.

SG-Link®-LXRS® inputs are 12-bit resolution with ± 0.1% full scale measurement accuracy. The node can log data to internal memory, transmit real-time synchronized data, and it supports event driven triggers with both pre- and post- event buffers.

To acquire sensor data, the SG-Link®-LXRS® is used with any LORD MicroStrain® data gateway, such as the WSDA®-Base -10 x-LXRS™ and WSDA®-1500 - LXRS®. The LORD MicroStrain® Node Commander® software is used for node configuration and data collection, and the optional SensorCloud™ web platform for data visualization and analysis. Users can also design custom programs with the open source LORD MicroStrain® Wireless Sensor Networks Data Communications Protocol.

Figure 1 - SG-Link®-LXRS® Wireless Sensor Node
2.1 Components List

The SG-Link®-LXRS® features an internal antenna and an integrated terminal block for attaching sensors. There are no removable parts. For a complete list of available configurations, accessories, additional system products and ordering information see Parts and Configurations on page 95.

Table 1 - Components List
2.2 Interface and Indicators

The SG-Link®-LXRS® includes a power input jack for charging the internal battery or externally powering the node, a power on/off switch, a power source selector switch, terminal blocks for connecting sensing devices and power, and mounting holes for device installation. The radio frequency (RF) antenna is internal to the node.

The indicators on the SG-Link®-LXRS® include a device status indicator, a battery charging indicator, a completed charge indicator, and a charge source indicator. The following table describes basic indicator behavior. During data acquisition, the device status indicator has other sequences (see Device Status Indicators on page 81).

Table 2 - Indicator Behaviors
3. System Operational Overview

![WARNING]

The SG-Link®-LXRS® contains an internal, rechargeable Lithium Polymer (Li-Po) battery. For important precautions see Safety Information on page 104.

![CAUTION]

The SG-Link®-LXRS® is susceptible to damage and/or disruption of normal operation from Electrostatic Discharge (ESD). For important precautions see Safety Information on page 104.

To acquire sensor data, nodes are used with any LORD MicroStrain® data gateway, such as the WSDA®-Base -10x-LXRS™ or WSDA®-1500 - LXRS®, and a software interface.

LORD MicroStrain® has two software programs available for the Wireless Sensor Network: SensorCloud™ and Node Commander®. SensorCloud™ is an optional web-based data collection, visualization, analysis, and remote management platform based on cloud computing technology. Node Commander® is used for configuring gateways and nodes, selecting sampling modes and parameters, initializing data acquisition, and viewing and saving data.

In this section system hardware and software setup is described, including an overview of the Node Commander® software menus required to configure a sensor connected to the node and begin data acquisition through the gateway. It is intended as a quick start guide and is not a complete demonstration of all system or software features, capabilities, or settings. Refer to the Node Commander® User Manual, the LORD MicroStrain® website, and the SensorCloud™ website for more information (see References on page 107).

- For an example of sensor configuration and a calibration routine, or for verification of system functionality, see Using the Node Tester Board on page 82.
- For instructions on connecting specific sensors, see Connecting Sensors on page 33.
NOTE

To maximize operating time, it is recommended that the SG-Link®-LXRS® internal battery be fully charged before installation. If fully discharged, it takes approximately 6 to 8 hours to achieve a full charge. For charging instructions see Charging the Node Battery on page 74.

3.1 Software Installation

To install Node Commander® Software Suite on the host computer run the installer executable file and follow the on-screen prompts for a complete installation.

NOTE

The Node Commander® software includes hardware drivers required for use with USB gateways. Once installed, the software will automatically detect and configure any USB gateways that are plugged into the host computer.

The Node Commander® Software Suite is included with all data gateways and is also available on the LORD MicroStrain® website for download. It includes the following programs:

- **Node Commander®** is used for configuring nodes and acquiring, viewing, and saving data.
- **Live Connect™** is a TCP/IP-to-serial conversion tool that translates the communications between Node Commander® and an Ethernet gateway.
- **WSDA® Data Downloader** is used to download acquired data from the flash memory card embedded in an applicable gateway, to a host computer.

SensorCloud™ is an optional data collection, visualization, analysis, and remote management tool. It is based on cloud computing technology and is accessed directly from a web connection. Because it is web-based, SensorCloud™ requires no installation. For more information see Data Handling on page 25.
3.2 System Connections

To acquire sensor data the following components are needed: user-supplied external sensors (as applicable), a LORD MicroStrain® wireless sensor node, a LORD MicroStrain® data gateway and a local or networked host computer with access to the data acquisition software (such as Node Commander® and SensorCloud™). For a connections overview refer to Figure 3 - System Connections.

Nodes will communicate with any LORD MicroStrain® data gateway. The sensor, node, gateway and software selection is application-dependent, but the basic interfaces are the same. Communication protocols between the gateway and host computer vary depending on which model gateway is used, but they all require interface to a host computer or network. The WSDA®-Base -10x-LXRS™ gateway utilizes local serial connections to the host computer, such as RS232 and USB, and interfaces with the Node Commander® software. The WSDA®-1500 - LXRS® gateway utilizes Ethernet communications and can be used with Node Commander® and SensorCloud™, although system configuration is completed using Node Commander®. Gateways with analog outputs can be connected directly to stand-alone data acquisition devices for data collection, however system configuration will still occur through a USB interface to Node Commander®.

Users can also write custom programs by utilizing the LORD MicroStrain® Wireless Sensors Network Software Development Kit (see References on page 107).

Figure 3 - System Connections
3.3 Gateway USB Communication

The USB gateway is used as an example in this quick start section. For information on how to use other gateways, refer to the gateway or Node Commander® user manual (see References on page 107).

For USB gateways, drivers need to be installed on the host computer. These drivers are included with the Node Commander® software. After the software is installed, the USB gateway will be detected automatically when the gateway is plugged in.

1. Open the Node Commander® software.

2. Make all hardware connections (see System Connections on page 13). Power is applied to the gateway through the USB connection. Verify the gateway status indicator is illuminated.

3. Open Node Commander®.

4. When connected, the gateway should appear in the Controller window automatically with a communication port assignment (Figure 4 - USB Gateway Communication). If it is not automatically discovered, verify the port is active.

![Figure 4 - USB Gateway Communication]
3.4 Connect to Nodes

To establish communication with the nodes in Node Commander® several methods can be used. This quick start section covers the two simplest methods for establishing node communication: adding a node by address and by using the node discovery feature.

3.4.1 Adding a Node by Address

Adding a node by address requires the node to be on the same communication frequency as the gateway. The node address and frequency are indicated in the documentation included with the node when it is purchased.

1. To add a node by address, right-click on the gateway name in the Controller window, and select Add Single Node (Figure 5 - Adding a Node by Address).

2. Enter the node address, and select OK. If the node is not found, a message will appear and provide the option to scan for the node on other frequencies. Once communication has been established, additional node information can be viewed by selecting the “+” symbol next to the node name.

Figure 5 - Adding a Node by Address

3.4.2 Using Node Discovery

The node discovery feature allows connection between the gateway and node to occur even if they are on different frequencies. To connect to nodes using node discovery, the nodes must initially be powered off.
NOTE

Automatic node discovery may not work in some boot-up modes. If the node is not in normal boot up mode, the assigned one can be bypassed to enable node discovery. For more information see Troubleshooting on page 76.

1. Right-click on the gateway name and select Add Node > Node Discovery.

Figure 6 - Adding a Node in Node Commander®

2. Turn the node on with the node power switch. During power-up, the node will transmit a message with its operating frequency within a few seconds.

3. When the device status indicator on the node ends the rapid flash sequence and begins pulsing at one-second intervals, it has completed the normal boot-up sequence and is running in idle mode. At this point the node should be listed in the Controller window, and scanning can be stopped by selecting the Stop button in the Node Discovery window. Additional node information can be viewed by selecting the “+” symbol next to the node name. If the information list appears, communication has been established (Figure 7 - Node Discovery).

Figure 7 - Node Discovery
3.5 Channel Configuration

The sensor settings are stored in the node memory of the node channel it is connected to. Only the channels and configuration options that are available on the type of node being used will appear in the configuration menus.

1. To enter the configuration menu, right-click on the node name, and select Configure > Configure Node. The Channels tab displays channel options available for the node.

   a. **Channel Enabled:** indicates the channel number. The check box is used to enable the channel and select it for sampling. The icon next to the check box describes the channel type intrinsic to the node being used. In the following example (Figure 8 - Node Channels Menu): a1) analog differential channel icon, a2) analog single ended channel icon, and a3) temperature channel icon.

   b. **Current channel configuration:** The Data Output, Units, Input Range, and Label fields describe how the channel is currently configured.

   c. **Configure:** Select the channel's Configure button to change the channel parameters, such as measurement units, gain and offset settings, and calibration values. The channel must be enabled first by selecting its adjacent check box.

![Figure 8 - Node Channels Menu](image)
2. To enter the channel configuration menu, select the Configure button as shown in *Figure 8 - Node Channels Menu*. The channel configuration menu options change depending on the sensor type selected.

   a. **Channel Label**: names the channel
   
   b. **Channel diagram**: shows the channel electronics and data flow
   
   c. **Conversion Coefficients**: defines the type and units of the measurement being made
   
   d. **PGA Settings**: These settings determine what gain is applied to the sensor measurement and set the position of the no-load baseline measurement for the sensor signal. It is only available for differential input channels with gain amplifiers.
   
   e. **Calibration values**: includes the slope, offset, scale, and formula used to convert the sensor reading to engineering units. The slope and offset can be determined from the sensor manufacturer calibration data or through a calibration process.

![Figure 9 - Channel Setup](image)
3.6 Sampling Settings

The SG-Link®-LXRS® has four primary sampling modes: Synchronized Sampling, Low Duty Cycle Sampling, Streaming, and Datalogging. Some modes have user-configurable settings for sample rate, sample duration, event-based sampling, and datalogging. Other settings are automatic, depending on number of active channels and other variables. For more information on sampling modes refer to the Node Commander® user manual (see References on page 107).

NOTE

Streaming mode (which is continuously sampling and transmitting) uses a large amount of system bandwidth and can significantly reduce node battery life. Streaming is recommended primarily for diagnostics and is not supported in SensorCloud™.

In general, when determining which sample mode and rate is most suitable for the application, consider the following:

- Increasing the sample rate reduces the available over-the-air transmission bandwidth and therefore also reduces the number of nodes that can be reporting simultaneously.

- Increasing the sample rate increases the power requirement of the node and therefore reduces battery life.

- When measuring vibration or other analog signals, it is important to use a sample rate at least twice the value of the target measurement frequency. This is the minimum sample rate required to produce an accurate digital representation of the measured signal. The higher the sample rate the more accurate the digital representation.
Sampling settings are accessed through the Configure Node menu. There is a tab for each sampling mode available for the particular node (Figure 10 - Sample Settings Menu).

![Sample Settings Menu](image)

**Figure 10 - Sample Settings Menu**

### 3.7 Data Acquisition

**NOTE**

Once sampling has started it will continue as configured without the need to leave Node Commander® open. However, if the node is powered off and is not configured to sample on boot-up, data acquisition will end and must be restarted in Node Commander®.

**NOTE**

Touching sensors and test boards or charging the node battery while acquiring data may induce noise on sensitive sensor signals and is not recommended.

When data acquisition is started, each of the sampling modes has different menu options and views. Some have a settings menu before data acquisition begins and may include a data list.
view and/or a graph view. The following is an example of Synchronized Sampling (Figure 11 - Starting a Sampling Session). For more information about synchronized sampling and using the gateway beacon see Data Acquisition on page 20. For more information about other sampling modes, refer to the Node Commander® user manual. (see References on page 107).

To start a sampling session, nodes can be selected individually or as a group. When selected as a group, they will all be set to the same sampling mode. Right-click on the nodes and select Sample. The menus are different, depending on which method is selected.

![Image of Node Commander interface](image)

**Figure 11 - Starting a Sampling Session**

When a synchronized sampling session is started, the sampling menu appears and includes settings to enable optional sampling features, configure nodes, and specify where the data is saved. The built-in bandwidth calculator displays the total bandwidth used by the nodes selected for synchronized sampling (Figure 12 - Synchronized Sampling Menu).

a. **Save Location:** indicates where the data file will be saved on the host computer. Use the Browse button to select a preferred location.

b. **Node configuration:** includes the node serial number, sampling settings, bandwidth calculation, and current status. Highlight any node or group of nodes, and the Remove, Configure, and Refresh buttons become active. The Configure button opens the node configuration menus to adjust settings as needed, and recalculates the node bandwidth. Multiple nodes can be configured together by using the Shift or Ctrl key to select them.
c. **Lossless**: enables the lossless data protocol. The protocol enables buffering and retransmission of data in order to provide 100% data collection success. Using this feature may increase data display latency.

d. **High Capacity**: reduces the transmit rates in order to optimize bandwidth and power savings among nodes with slower sample rates.

e. **Network Bandwidth**: is the total bandwidth used by all the nodes.

f. **Enable Beacon on Start**: This setting is the same as enabling the beacon in the gateway menu and by default is selected. As soon as sampling is started the nodes wait for the first beacon transmission to initiate sampling. When this option is selected, the gateway beacon is enabled and will begin transmitting at a fixed interval at this time. Disabling the beacon on start (unchecking the box) will set the nodes to wait for the beacon, but does not actually start the beacon. This can be used if there is a need for sampling to be initiated later, or if the beacon is being received from another source than the gateway. Refer to the Node Commander® User Manual for more information.

g. **Apply settings and start sampling**: Before acquisition can begin, use the Apply Network Settings to save the session settings to the node. When completed, select Start Sampling to begin.
h. Close sampling window with the red "X" to exit sampling or, once the sampling has been started, to view the data window behind it.

Synchronized sampling features two data views: a grid view and a graph view. Once sampling is started, the data grid view is the default view.

NOTE

Depending on the synchronized sampling settings, it may take many seconds before the first sample to appear in Node Commander®.

Figure 13 - Synchronized Sampling Data View

a. Device status: Node sampling mode and gateway status are displayed in parentheses next to the device name.

b. Node information: includes node serial number and sampling statistics. Right-click on the node name for more menu options such as Stop Nodes.

c. Data: display of the sampled data with each channel in a column

d. Radio strength: indicates how good the communication is between the gateway and node. See Range Test on page 32.

e. Data file: the location and size of the data file, as data is added. View the data in CSV format with the Open File button.

f. View menu: Select between Data Grid and Graph views.
g. **End sampling:** The red "X" is used to exit the sampling window and/or end sampling.

Use the view menu to select the Graph view of the data. Click on the node to view the graph for that node. Click again to hide it.

---

**Figure 14 - Synchronized Sampling Graph View**

a. **Available Nodes:** Click on the node to display the graph for that node. Click again to hide it. Right-click on the node name for more menu options such as stop nodes and save stream.

b. **Axis range:** Select the X-axis width and Y-axis zoom percentage, or use the Auto check box for automatic scaling.

c. **Graph:** The node graph shows the sampled data. Each active channel is displayed as a different color. The X-axis is time in seconds and the Y-axis is the A/D value (bits). Right click on the graph for additional menu options such as View Graph Key, Pan, Zoom, Pause, and Remove Graph.

d. **View menu:** Select between Data Grid and Graph views.

e. **Data file:** The location and size of the data file as data is added. View the data in CSV format with the Open File button.

f. **End sampling:** The red "X" is used to exit the sampling window and/or end sampling.
3.8 Data Handling

Data acquired through Node Commander® is automatically saved on the host computer (see Sensor Data Files on page 28) and can also be viewed from the web-based SensorCloud™ portal. Saved data can be uploaded to SensorCloud™ and Ethernet gateways provide the option to automatically port the data to SensorCloud™ during data acquisition for near real-time display and aggregation. Ethernet gateways can also be configured to save data locally to internal memory for future upload to the host computer or SensorCloud™.

SensorCloud™ is based on cloud computing technology and is designed for long term collecting and preservation of data. Features include time series and visualization graphing, automated alerts, and data interpretation tools such as data filtering, statistical analysis, and advanced algorithm development with the integrated MathEngine® interface. Leveraging the open source API, SensorCloud™ can also be used to collect data from other LORD MicroStrain® sensor products or third-party systems. Basic SensorCloud™ services are available to all users free of charge (see Connect to SensorCloud™ on page 26).

Figure 15 - Data Storage, Display and Processing
3.8.1 Connect to SensorCloud™

If the gateway is enabled for SensorCloud™ access and the sensor node sampling has been activated, data will automatically upload to the web. Data from the gateway can also be uploaded to SensorCloud™ once logged on.

To connect to SensorCloud™ go to the SensorCloud™ website log-in page, and enter the log-in credentials. Register as a new user if needed.

http://sensorcloud.com/log-in/

Figure 16 - SensorCloud™ Log-in or Register

The SensorCloud™ interface has six main views. When logging in as a registered user, the Device view is the default. Navigate to other views by clicking the view name at the top of the page (Figure 17 - SensorCloud™ Device Menu).
a. **Device** - The device list shows every gateway and API device associated with the SensorCloud™ account, including owned, shared, and demo devices. This view provides links to each devices SensorCloud™ subscription plan, device configuration options, and a summary of last communications and data transactions.

b. **Account** - The account view is for logistic management of the SensorCloud™ account, such as changing the log-in password, user email, and billing information.

c. **CSVUploader** - The data upload feature enables data from any source (such as non-Ethernet LORD MicroStrain® gateways, or third-party sensors) to be uploaded for display in SensorCloud™. The data should be in the LORD MicroStrain® CSV format.

d. **Data** - The data view is the data visualization page and displays data collected from sensor nodes or uploaded from files. Sensor data selections are listed by the node channel or user-defined label and can be enabled for display in the graph window. The interactive graph has navigational features such as panning, zooming, and an overview graph for single click access to data points or ranges.

In the data view there are also data use and management features such as viewing the meta-data and downloading, embedding, and tagging data graphs *(Figure 18 - SensorCloud™ Data View)*.

![Figure 18 - SensorCloud™ Data View](image-url)
e. **Settings** - The settings view provides options for adding meta-data, configuring the data displays for each channel, creating alerts based on data thresholds, and setting the data timezone and more.

f. **MathEngine** - is used to analyze sensor data. Functions include the ability to filter out frequencies, smooth out noisy data, perform math operations such as Fast Fourier Transforms (FFTs), and much more. MathEngine interfaces with the SensorCloud™ graphing view for faster processing (Figure 19 - MathEngine® View). Refer to the MathEngine® website for more information

http://sensorcloud.com/mathengine

![Figure 19 - MathEngine® View](image)

For more information about SensorCloud™ features and navigation, refer to the SensorCloud™ website or contact LORD MicroStrain® Technical Support (see Technical Support on page 93).

### 3.8.2 Sensor Data Files

Data acquired in Node Commander® is stored in CSV format and can be opened with Microsoft Excel, Quattro Pro, Open Office, or other CSV editors/spreadsheet programs. Data in this format is very easily uploaded to SensorCloud™ as well using the SensorCloud™ CSV Uploader. The data files can be found on the host computer in the default directory or the location specified at the beginning of sampling (as applicable).
The default directory is: `C:\ProgramData\Microstrain\NodeCommander\SampledData`

Different sampling modes will output different file types, and they will be categorized in separate folders by sampling mode and then further categorized by date, session, and/or node serial number.

**Synchronized sampling and low duty cycle files** are found in the Sampled Data folder.

**Datalogging files** need to be downloaded from the node before they are available for viewing and can be accessed through datalogging menus as well as the File menu. They are stored by default in the Downloaded Triggers folder.

**Streaming data** is stored in the Streaming folder.

![Figure 20 - Exploring Data](image)

**NOTE**

The Microsoft Excel the Time data column in the data file may have to be changed to "m/d/yyyy h:mm:ss:000" format to make it more readable.
4. Node Installation

4.1 Mounting Recommendations

The SG-Link®-LXRS® is rated for indoor use only, unless housed in a ruggedized outdoor enclosure. Enclosures for the SG-Link®-LXRS® are available from LORD MicroStrain®. Some also accommodate D cell batteries, extending the battery operating capacity and duration. For more information see Node Accessories on page 96.

There are two mounting tabs on the node, with holes for fastening.

The node can be mounted in any orientation, but it is recommended that it is mounted in a way that optimizes wireless communications. For more information see Optimizing the Radio Link on page 31.

Figure 21 - Mounting the Node
4.2 Optimizing the Radio Link

In ideal conditions, the nodes and gateway can communicate up to two kilometers apart. In order to accomplish this, the node and gateway must be installed in a manner that optimizes the wireless transmission. The SG-Link®-LXRS® operates at a 2.4GHz transmission frequency. The internal antenna has an omni-directional radiation pattern. Using any other antenna with the node will void FCC compliance.

The best method for ensuring optimal radio communication is to conduct an RF survey of the installation site. This is easily accomplished in Node Commander® by using the range test feature to quantify the radio signal strength (RSSI) in various scenarios. See Range Test on page 32 for instructions on using Node Commander® for measuring RSSI. The following are general guidelines for maximizing transmission range:

- **Establish Line of Sight (LOS)** between the node and gateway antenna as best as possible. Try to avoid obstructions between the antennas, such as buildings, terrain, vegetation, or other physical barriers. Increase the mounting height of the node to allow a clearer LOS path to the gateway. Height above the ground is also important because reflections off of the ground can interfere at the receiver. Generally, the higher above the ground the better.

- **Minimize Radio Frequency Interference (RFI)** such as other equipment antennas, especially those operating in the same frequency range. This includes other nodes. If other antennas are required nearby, mount them at different heights to minimize interference. Additionally, the specific node frequency is selectable within its operational range using the Node Commander® software. Set the devices to different transmission frequencies.

- **Minimize Electromagnetic Interference (EMI)** such as that which is generated by power transmission equipment, microwaves, power supplies, and other electromagnetic sources.

- **Metal Objects** in close proximity to either antenna, especially ferrous metals such as steel and iron, can be problematic for wireless communications. The larger the object, the greater the influence.
4.2.1 Range Test

After establishing communication between node and gateway, use the range test in Node Commander® to monitor the signal strength and to optimally position the nodes, gateway, and antennas for installation. Maximum achievable range is determined by the gateway and node power settings (found in the device Configure menu) and is highly dependent on the physical environment surrounding the devices.

1. Right-click on the node header, and select Communicate > Range Test.

![Figure 22 - Range Test Menu](image)

2. The total RSSI range for the node and gateway is -90 to 0dBm. The higher the value (closer to zero), the better, but reliable communication can be achieved between -75 dBm and 0 dBm. The devices is still able to communicate between -90 dBm and -75 dBm, but it could be intermittent or result in data loss. Position the node and gateway antennas where the best RSSI value is observed.

![Figure 23 - Range Test Statistics](image)
5. Connecting Sensors

The SG-Link®-LXRS® contains an internal, rechargeable Lithium Polymer (Li-Po) battery. For important precautions see Safety Information on page 104.

The SG-Link®-LXRS® is susceptible to damage and/or disruption of normal operation from Electrostatic Discharge (ESD). For important precautions see Safety Information on page 104.

The SG-Link®-LXRS® wireless sensor node features two analog input channels that interface with a wide range of available sensor technologies, essentially converting them into wireless sensors. The node accommodates Wheatstone Bridge and analog sensors for applications in wireless strain gauge monitoring, such as torque, force, and pressure measurement, as well as sensors for other applications like wireless accelerometers, vibration sensors, magnetic field and displacement sensors. Environmental sensing can be achieved with wireless RTD and wireless thermocouple monitoring.

The SG-Link®-LXRS® includes one channel for single ended sensor measurement, one channel for differential sensor measurement, and an additional channel dedicated to the on-board internal temperature sensor. Differential channels may need to be factory-set to work for specific types of sensors. For information about channel configurations see Differential Input Channels on page 38. For ordering information see Parts and Configurations on page 95.

5.1 Sensor Requirements

Below are guidelines for selecting sensors for use with the SG-Link®-LXRS®. For interfacing with sensors outside of these parameters, or not included in the examples in the following sections, contact Technical Support (see Technical Support on page 93).

Sensor Impedance:

- Differential input sensors for a standard SG-Link®-LXRS® should have an impedance of either 350 Ω or 1000 Ω. Sensors that are 120Ω are not recommended. For half-bridge and quarter-bridge configurations, the node impedance value is set to
match the sensor when the node is manufactured and must be specified at the time of order. For more information see Parts and Configurations on page 95. Custom bridge completion impedance values are available on request.

- Single ended sensor inputs must have impedance that is less than 5KΩ.

**Sensor Signal Voltage:**

- Differential sensor inputs include a hardware gain and offset stage before the sensor input signal is processed by the analog to digital voltage converter within the node. The combination of the gain, offset, and sensor signal voltage cannot exceed the 0 to 3 V dc input range of the analog to digital converter. For more information see Differential Input Gain and Offset on page 56.

- Single-ended sensor signal voltages can only be positive voltages with respect to the system ground and must be between 0 and 3 V dc. For single-ended sensor signal voltages outside of that range see Measuring Voltages over Three Volts on page 44.

**Sensor Power:**

- When using the internal node battery as the node power source, the total current use for all connected sensors must be less than 50mA. If more current is required, a higher capacity external power source can be used for the node or the sensor. See Sensor Power on page 35 for information about sensor power requirement considerations and options, and see Powering the Node on page 71 for information regarding node power options.

5.2 Wiring Recommendations

In is good practice that all sensor wiring be done with shielded cable. The shield is connected to the system ground only at one end to avoid ground loops. For sensitive small voltage signals (such as strain gauges) sensor wire leads should be of matched lengths so the lead resistance for each connection is as close to the other as possible. For long lengths of wire, a system calibration is recommended over a sensor calibration. See Sensor Calibration on page 58.
5.3 Sensor Power

When using the internal node battery to power the node, total sensor current draw of more than 50mA can cause permanent damage to the node and should be avoided.

Sensors can be powered by the node or with an external power supply. The node sensor excitation voltage is 3 V dc and can provide up to 50 mA total on all channels. If a higher voltage or more current is required for the sensor, an appropriately sized external power supply can be used. For example, using the node battery for current intensive devices such as 4 to 20mA sensors will drain the battery quickly. For these applications, an external source is recommended for the sensor or the node. See 0 to 3 V dc Voltage Measurements on page 43 for an example of using an external source for the sensor, and see Powering the Node on page 71 for node power information.

Drain on the battery can also be limited by selecting low resource sampling modes and low duty sampling rates, which automatically switch the node excitation voltage off after sampling. This feature can also be utilized to turn switches on and off to further control resource use. See Using the Excitation Output as a Switch on page 46.

External battery holders and ruggedized outdoor housings that accommodate D cell batteries are available for the SG-Link®-LXRS® and can be used to extend battery operating capacity and duration. See Node Accessories on page 96.

5.5 Terminal Block Connections

When inserting the sensor leads into the terminal block, ensure the lead wire is being clamped under the terminal screw and not the lead insulation. If the sensor wires are a very fine gauge, folding and tinning them may be useful to provide more area for the terminal screw to make contact. Failure to provide adequate connection may result in erroneous data.

5.7 Differential Input Channels

NOTE

Differential channels are configured at the time of manufacture with optional Wheatstone Bridge configurations and impedance values and must be connected accordingly. For available options see Parts and Configurations on page 95.

The differential channels provide an input for sensors with a separate analog return. The measurements are taken with respect to the analog return, instead of the system ground, in order to provide better protection for small measurements from EMI, RFI, and other sources of signal noise. The primary use of these channels is for strain gauges, pressure transducers, load cells, and other devices that can utilize a Wheatstone Bridge configuration. The SG-Link®-LXRS® is available in standard configurations for full, half, or quarter Wheatstone Bridge operation, at various impedances. See Differential Sensors on page 39. Custom configurations are also available. For configuration and ordering options see Parts and Configurations on page 95.

The differential measurement channels provide a +3 V dc excitation voltage to the sensor and measures the resulting sensor signal output. The sensor signal goes through a programmable gain amplifier (PGA) and is then processed in the node by a 12-bit analog to digital (A/D) converter over the 3 V dc range. The resolution of the sensor measurement is dependent on the operating range of the sensor. If the application is such that only a small portion of the 3 V dc range is being utilized, better resolution can be achieved by increasing signal amplification and by zeroing the sensor baseline in the appropriate offset biasing range.

Figure 25 - Differential Channel Signal Processing
5.7.1 Differential Sensors

Sensors that are classified as differential sensors often utilize a Wheatstone Bridge configuration. These sensors are essentially a resistive load that use the bridge configuration to detect very small resistive changes and produce a precise voltage output as a result. Some examples include strain gauge elements or strain gauge-based sensors, such as some load cells and pressure transducers, as well as some soil moisture, temperature, and other sensors. For use with the SG-Link®-LXRS®, sensors with an impedance of 350Ω or 1000Ω are recommended.

Calibration in the Node Commander® software for these devices varies depending on the type of sensor and includes using the a calibration wizard for strain gauges. The following diagrams show how to connect these types of sensors. See Sensor Calibration on page 58 for more information.

![Diagram of Full-Bridge Wiring]

**Figure 26 - Full Bridge Wiring**
Figure 27 - Half and Quarter-Bridge Wiring
5.7.2 Measuring Small Voltages

Some sensor types that have small signal voltages (around 20mV or less) may be better measured by biasing the sensor signal to the mid range of the node input range with a voltage divider, as shown in Figure 28 - Small Voltage Measurement.

Channel configuration will include adjusting the gain setting accordingly in the Node Commander® software.

![Figure 28 - Small Voltage Measurement](image)

**KEY**
- x = channel number
- Rx = external resistor
5.8 Single-Ended Input Channels

Single-ended channels are designed to measure voltages with reference to the system ground and can accommodate many analog sensors types including accelerometers, pressure transducers, geophones, temperature sensors, inclinometers, and more. These channels can also be used to measure reference voltages.

Sensors that operate on 3 V dc can be powered with the node excitation voltage. Alternately sensors can be powered with an external source. For an example of how to connect an external supply see 0 to 3 V dc Voltage Measurements on page 43.

The single-ended channels can measure signals from 0 to +3 V dc with reference to the system ground. Sensor output must be positive going voltage in order to operate correctly with the SG-Link®-LXRS®. If the sensors output is greater than 3 V dc a voltage divider can be used to decrease the scale. See Measuring Voltages over Three Volts on page 44. The impedance of the sensor must be less than 5 KΩ.

The sensor output signal is processed in the node by a 12-bit analog to digital (A/D) converter, over the 3 V dc range. The resolution of the sensor measurement is dependent on the full scale output range of the sensor. The closer it is to three volts, the more resolution will be achieved.

The following sections provide examples of how various sensors can be connected to the node. For other applications or those outside of the operating parameters listed above, contact LORD MicroStrain® Technical Support (see Technical Support on page 93 for contact information).
5.8.1 0 to 3 V dc Voltage Measurements

Sensors that operate in the 0 to 3 V dc range are ideal for the node inputs. Resistive loads that are not differentially measured, such as string potentiometers, are easily measured by the node single-ended channels. Power is provided by the node excitation voltage and measured on a single-ended input, as shown below.

Reference power supply signals between 0 and 3 V dc can be measured by connecting directly between the signal input pin (Ainx) and ground (GND).

Sensors that have voltage requirements outside of the range of the node excitation voltage can be powered externally with another source. The sensor output can still be connected directly to the node input as long as it is between 0 and 3 V dc. For sensor outputs over 3 V dc see Measuring Voltages over Three Volts on page 44.

Figure 30 - 0 to 3 V dc Measurements
5.8.2 Measuring Voltages over Three Volts

Voltages over three volts can be measured with the use of a voltage divider circuit. This may be necessary if a sensor is powered from an external source. The same circuit can also be used to measure reference power supplies over +3 V dc.

The value of the voltage divider resistors will need to be determined, as required for the application. A 10KΩ resistor is recommended for the input to the node channel, leaving only one resistor to calculate.

CALCULATIONS:

\[ V_{in} = \text{maximum sensor output} \]
\[ V_{out} \leq 3 \]
\[ R_2 = 10 \text{KΩ} \]

by Ohms Law;

\[ V_{out} = V_{in} \left( \frac{R_2}{R_1 + R_2} \right) \quad \text{or} \quad R_1 = \left( \frac{V_{in} R_2}{V_{out}} \right) - R_2 \]

EXAMPLE:

\[ V_{in} = 0 \text{ to } 9 \text{VDC} \]
\[ R_1 = \left( \frac{9 \Omega \times 10000 \Omega}{3V} \right) - 10000 \Omega = 20 \text{KΩ} \]
5.8.3 Measuring Small Currents (4 to 20mA Sensors)

Sensors with small currents, such as 4 to 20mA sensors, can be used with the nodes by adding a precision sampling resistor across a single-ended input channel to the node. An example circuit is shown in Figure 31 - Small Current Measurements.

Because the sensor output can be as much as 20mA it is recommended that an external source be used to power the sensor. When running on the internal node battery, the node excitation can only supply 50mA to all sensors, so 20mA would be a significant portion and would drain the battery quickly. For battery life and current draw information see Using the Internal Node Battery on page 73. The current limitations can be mitigated by using an external power source for the sensor or the node. If using node excitation power is the best for the application, drain on the battery life can be limited by only switching the node excitation voltage on just before sampling and then turning it off afterward. This happens automatically at low duty sampling rates (32Hz or lower) and can be set up for other sample rates with external circuitry. For more information see Using the Excitation Output as a Switch on page 46.

![Figure 31 - Small Current Measurements](image)
5.9 Using the Excitation Output as a Switch

At low sampling rates (under 32Hz) the node automatically switches the excitation voltage output off when the sensor is not being sampled, in order to conserve battery life. This feature can also be used in applications where a switch is desired, such as for turning sensor power on and off when the sensor is powered by the node but has a large current draw. It can also be used as a general purpose switch, such as for controlling a relay or transistor. The same limitations apply as to a sensor; the device must operate on 3 V dc and not require more than 50mA when combined with all other sensor current draw. To use the excitation output in this way, connect the control line of the device (example: relay coil or NPN transistor base) to the excitation pin on the node terminal block (SP+) and reference (example: other side of the relay coil or the NPN transistor emitter) to the node ground pin (GND).

5.10 Thermocouples

Thermocouples can be used on the differential input channels by simply adding a high-impedance resistor to the input. An example circuit is shown in Figure 32 - Connecting a Thermocouple.

Thermocouples should be calibrated by first selecting the appropriate baseline offset range, output range, or gain and then applying known loads and calculating the slope and offset values. Using water as the known load medium (submerging the thermocouple in ice and hot water baths) is a simple method that can be used for calibration.

![Figure 32 - Connecting a Thermocouple](image-url)
5.11 On-board Temperature Sensor

- The SG-Link®-LXRS® has an on-board, solid state temperature sensor mounted on the surface of the circuit board.
- The temperature sensor output is connected to channel 3 of the SG-Link®-LXRS®
- The temperature sensor has a measurement range of -25°C to +70°C range with an accuracy of ± 0.5°C @ 25°C.
- The sensor is made by Texas Instruments (part number LM60). Specifications may be found on the manufacturer’s website.
6. Sensor Settings

LORD MicroStrain® sensor nodes are designed to accept many sensor types. The node configuration interface includes settings for measurement units, gain settings, and conversion values. For more information see Sensor Calibration on page 58. There are preset measurement units, as well as a user-defined field. Because the wireless sensor system is digital, the analog voltage readings from the sensors are converted into a digital equivalent value based on the volt-to-bit scale of the internal analog-to-digital voltage converter (A/D converter). Sensor readings can be displayed and recorded in volts and A/D value (bits) directly or further converted to engineering units by applying conversion values and a conversion formula. For more information see Conversion Values on page 51, and for instruction of adjusting units see Measurement Units on page 50.

Some sensors require calibration to determine more accurate conversion values. Calibration incorporates coefficients that normalize the sensor output to a known reference device and guarantee accuracy of conversions.

External sensors can be attached to any channel that is suitable for sensor type. Table 5 - Example External Sensor Types, describes example sensors, units, and calibration options.

Table 5 - Example External Sensor Types
6.1 Measurement Units

Sensor measurement units are set in the channel Configuration menu.

1. To enter the Configuration menu, right-click on the Node heading, and select Configure > Configure Node. The Channels tab displays channel options available for the current node.

![Figure 33 - Channel Configuration Menu](image1.png)

2. Select the type of measurement from the Class menu, and then select Units.

![Figure 34 - Select Sensor Units](image2.png)
6.2 Conversion Values

The conversion values can be determined mathematically from the sensor sensitivity specifications, from the sensor manufacturer calibration data, or through a calibration process. Calibration incorporates coefficients that normalize the sensor output to a known reference device in order guarantee accuracy of the sensor readings, especially when making small or precise measurements. See Sensor Calibration on page 58 for more information. Not all sensors require calibration.

The conversion values include the slope, offset, gain, scale, and formula for converting the sensor A/D value (bits) to engineering units. The bits are the digital representation of the sensor voltage output. The type of sensor, channel, and desired engineering units determine what conversion values are available. The conversion values are entered via the Node Commander® and saved in the node memory for the applicable channel.

The conversion values can be entered in two menus. The channel Configuration menu has more options than the Calibration Coefficients menu, but both are acceptable ways to enter the values and formulas.

![Figure 35 - Abbreviated Conversion Values Menu](image-url)
NOTE

In order to report accurate readings, many sensors require calibration. Calibration coefficients normalize the sensor output to a known reference device and are often expressed in the measurement unit conversion values; the only difference being the use of a traceable reference. Calibration can be used to account for the variations between individual sensors, wiring, system electronics, sensor mounting and environmental conditions.

Conversion Formula: The conversion formula assumes a linear relationship between the original units (such as volts or A/D bits) and new engineering units (such as strain), and it is expressed mathematically as \( y = mx + b \), where \( y \) is the engineering units at a given point (measurement), \( m \) is the slope of the line that represents the linear ratio, \( x \) is the original unit value at a given point, and \( b \) is a unit conversion offset (in the case of unit conversions) or the fixed zero load offset of the sensor (in the case of measurement calibration coefficients). Negative values may be entered for any coefficient.

Slope: is the linear scaling slope coefficient. The slope is the ratio of original units to new engineering units (EU), and it is used to convert the sensor measurements. The slope conversion value will vary depending on the engineering units desired. For example if the original unit is A/D values (bits), and the desired engineering units are acceleration in g-
force, the slope conversion would describe how many bits equal one unit of \( g \)-force (bits/g). Mathematically, the slope is \( m \) in the formula \( y = mx + b \).

**Offset**: is the linear scaling offset coefficient, and it is typically the starting output value of the sensor with no load applied (in the original units). Mathematically, the offset is \( b \) in \( y = mx + b \).

**Effective Range**: the effective range is the calculated sensor measurement range in engineering units (EU). The effective range is dependent on the slope, offset and resolution of the node. The effective range is the number of bits per EU unit (slope) multiplied by the total number of bits, minus the offset (if applicable).

**Input Range (Gain)**: This sets the amplification of the signal within the node and is only available for channels with differential inputs and gain amplifiers.

**Offset Scale (with Auto Balance)**: This feature is only available for channels with differential inputs, and assigns the position and value of the no load measurement of the sensor. The offset scale level adjusts the operating window of the sensor measurements in reference to the entire range. For example, in mid scale the sensor no load measurement will be placed in the middle of the range, providing 50% of the range for positive readings and 50% of the range for negative readings. Once the scale level is selected, the Auto Balance procedure is used to assign the actual sensor no-load measurement to the designated scale.

- Low is for positive-going signals (zero at 25% of total range).
- High is for negative-going signals (zero at 75% of total range).
- Midscale is for positive and negative-going signals (zero at 50% of range).

![Figure 37 - Offset Scale Setting](image)
6.2.1 Calculating a Linear Slope

A data analysis tool, such as Microsoft Excel, can be used to determine the slope of a linear relationship between sensor output A/D value (bits) and engineering units. This is not a calibration, unless a calibrated reference device is used to measure the applied loads. For information and examples for determining calibrations coefficients see Sensor Calibration on page 58.

Here is an example, using Excel:

1. Open a blank spreadsheet.

2. Enter the A/D value (bits) measurements and applied load in the desired engineering units in two columns. Enter A/D value is in the left column (x-axis value) and the applied load in the right (y-axis value).

3. From the Insert menu, select Chart > Scatter. Select the preferred format.

Figure 38 - Generate a Scatter Chart
4. Right-click on the graphed line, and select Add Trendline.

5. Designate the line as Linear, and check the option to Display the Equation on the chart.

![Plot Trendline](image)

**Figure 39 - Plot Trendline**

6. The formula of the line is \( y = mx + b \), where \( y \) is the engineering units at a given point (measurement), \( m \) is the slope of the line that represents the linear ratio, \( x \) is the A/D value at a given point, and \( b \) is the fixed zero load offset of the sensor. Enter the slope and offset as the conversion values for the sensor channel under the applicable engineering units. In this example, enter 0.1338 for the slope and -282.36 for the offset for the pounds units conversion values on the measured channel.

![Slope and Offset Values](image)

**Figure 40 - Slope and Offset Values**
6.2.2 Differential Input Gain and Offset

The combination of the gain, offset, and sensor signal cannot exceed the 0 to 3 V dc input of the analog to digital converter within the node. See Example Gain and Offset Calculations on page 57.

- **Resolution**: Applying gain to the sensor signal can be used to maximize the measurement resolution. The more of the range that is used, the more digital counts are available to measure the signal, which typically means higher resolution measurements. Limitations to the gain adjustment are the sensor's measurement capabilities and the 0 to 3V input range of the node. The signal produced after gain is applied to the sensor at full scale must not exceed the input range of the node.

- **Offset Scale**: The scale setting positions the no-load measurement of the connected sensor within the 0 to 3V range of the node input. The range of A/D counts that corresponds with the 0 to 3V node input depends on the resolution of the node. For example, a 12-bit node will have a full scale bit range of 4096 and a 16-bit node will have a full scale bit range of 65535. A mid-range setting positions the baseline offset in the middle of the range (1.5V or full scale bits*1/2) and is used for sensors with negative and positive going signals. The low-range setting positions the baseline offset in the bottom quarter range (75mV or full scale bits*1/4) and is used for sensors with mostly positive going signals. The high-range setting positions the baseline offset in the top quarter of the range (2.25V or full scale bits*3/4) and is used for mostly negative going signals.

![Figure 41 - Differential Input Resolution and Offset (16-bit Node)](image-url)
6.2.2.1 Example Gain and Offset Calculations

EXAMPLE 1:

Sensor signal range: 0 to 50mV
Gain setting: 21
Baseline offset range setting: Mid-range

Calculations:

\[ 50\text{mV} \times 21 = 1.05\text{V} \] (maximum voltage of sensor signal with gain)
\[ 1.05\text{V} + 1.5\text{V} = 2.55\text{V} \] (maximum input voltage to node with gain and offset)

**Calculated node input over sensor range:** 1.5 to 2.55V

This is a good setting because the node input voltage is within the 0 to 3V range.

EXAMPLE 2:

Sensor signal range: 0 to 50mV
Gain setting: 30
Baseline offset range setting: Low-range

Calculations:

\[ 50\text{mV} \times 30 = 1.5\text{V} \] (maximum voltage of sensor signal with gain)
\[ 1.5\text{V} + 75\text{mV} = 2.25\text{V} \] (maximum input voltage to node with gain and offset)

**Calculated node input over sensor range:** 75mV to 2.25V

This may be a better setting than in Example 1 because the gain is higher, which could increase the resolution of the measurement. The node input voltage is still within the 0 to 3V range.

EXAMPLE 3:

Sensor signal range: 0 to 50mV
Gain setting: 75
Baseline offset range setting: Low-range

Calculations:

\[ 50\text{mV} \times 75 = 3.75\text{V} \] (maximum voltage of sensor signal with gain)
\[ 3.75\text{V} + 75\text{mV} = 4.5\text{V} \] (maximum input voltage to node with gain and offset)

**Calculated node input over sensor range:** 75mV to 4.5V

This setting will not work because the node input voltage is outside of the 0 to 3V range.
### 6.3 Sensor Calibration

Many sensors require calibration coefficients to accurately report measurements. Methods for determining the calibration coefficients depend on the type of sensor measurement and application. The Node Commander® software facilitates multiple calibration methods. Calibration calculators for some applications are also available by contacting LORD MicroStrain® Technical Support. See Technical Support on page 93.

- **Sensor manufacturer’s specifications or calibration:** The slope and offset values, or the data to derive them, are provided with the sensor by the manufacturer to prove its accuracy and describe expected voltage output. Some sensors are calibrated individually, while others are manufactured to a standard sensitivity value (plus or minus some tolerance), which is provided in the device specifications.

- **Sensor lab calibration:** If the manufacturer’s calibration is not available or outdated, calibration of the sensor can be performed with calibrated equipment in a controlled environment. The calibration equipment and process will typically be traceable to an industry standard, such as NIST or ASTM in the United States. Fixed loads are applied to the sensor while the sensor output is recorded. The load is applied or measured by a calibrated reference device. The known load value from the calibrated device is then plotted against the measured output of the sensor to determine the calibration slope and offset. In Node Commander® this can be accomplished by taking sensor readings while applying the known loads.

Sensor wiring, tolerances in system electronics, and differences in mounting techniques are examples of systemic variables that can influence the sensor readings. Sensors that are making small measurements or are otherwise sensitive to these slight differences may benefit from a system calibration. The following techniques are system calibrations:

- **System shunt calibration (internal and external):** This option is only available for Wheatstone bridge-type sensors (such as strain gauges) and utilizes a calibration wizard in Node Commander®. In the shunt calibration process, an internal or external precision resistor is used to load part of the sensor bridge while the sensor remains unloaded. The bridge output is measured and used as a loaded calibration point for the sensor. In addition to the no-load value it can be used to derive the calibration slope and offset. The internal shunt resistor is suitable for most applications, however an external shunt may be beneficial in high gain scenarios.
- **System field calibration:** The field calibration is a similar methodology to the sensor lab calibration. Known loads are applied to the sensor while the sensor output is recorded. The load is applied or measured by a reference device. In this scenario, the sensor may be installed in final field configuration, and the load may be applied with the actual stimulus that the sensor will be monitoring. The known load value from the reference device is then plotted against the measured output of the sensor to determine the calibration slope and offset. In Node Commander® this can be accomplished by taking sensors readings while applying the known loads.
6.3.1  EXAMPLE: Lab or Field Calibration

The lab and field calibrations use similar methodology. See Sensor Calibration on page 58. The primary difference is the traceability and calibration environment. Lab calibrations are performed in controlled environments with traceable equipment and procedures. Field calibrations are more improvised, although calibrated equipment can still be used to improve accuracy.

**NODE:** V-Link®-LXRS®, 16 bit (65536 A/D values)

**CHANNEL TYPE:** differential analog input, 0 to 3 V dc input range

**SENSOR TYPE:** load cell

**SENSOR PARAMETERS:** application voltage range: +/-20mV

This is the expected output voltage of the sensor based on the range of force being measured in the application and the sensitivity of the sensor (V/engineering units)

**DESIRED OUTPUT:** engineering units (EU), force (lbs)

**PROCEDURE:**

1. Open Node Commander®, and establish communication with the gateway and node (see System Operational Overview on page 11).

2. Right-click on the node heading and select Configure > Configure Node. Select the check-box for Channel 1, which is where the strain gauge is connected, and then select the Configure button.

**Figure 42 - Node Configuration Menu**
3. Use the following settings (*Figure 43 - Channel Settings*):

   a. **Conversion Coefficients, Class:** A/D value
   
   b. **Conversion Coefficients, Units:** bits
   
   c. **PGA Settings, Hardware Gain:** 104
   
   d. **PGA Setting:** Midscale (for positive and negative going signals)

4. Select the Auto Balance button to tare the no-load value of the strain gauge. Click OK to apply the node settings and exit configuration.

![Figure 43 - Channel Settings](image)

5. Right-click on the node heading, and then Sample > Stream > Start.

![Figure 44 - Start Node Streaming](image)
6. The streaming graph shows the bit output of the channel.

7. Using a calibrated tool (or some other way of applying and measuring a known load) and apply loads to the sensor at a number of intervals over the expected range of use. At each of the calibration intervals, record the applied force and the corresponding sweep value on the y–axis of the graph (the A/D value output of the sensor).

   a. Zoom in and out on the graph by un-checking the Auto Y-Axis Zoom box, and then right clicking on the graph and selecting Zoom In. Draw a box around the desired area to zoom in on.

   b. Adjust the Y-Axis Width from the field next to the Y-Axis Zoom.

   c. End sampling by clicking the red X box on the Streaming Graph tab.

![Figure 45 - Node Sampling](image)
8. After making all measurements, calculate a slope from the data using the formula $y=mx+b$ in a data analysis program, such as Microsoft Excel. *See Calculating a Linear Slope on page 54.*

9. Return to the Node Configuration screen for the sensor channel, and select the Conversion Coefficients Class and Units, and enter the Slope and Offset values derived in the data analysis program.

![Figure 46 - Enter Calibration Values](image)

10. Save the values, and exit configuration. This is the end of a lab calibration.

11. For field calibrations, begin node data streaming again with no load on the sensor.

12. Observe the value in the stream graph. If the stream is not at zero, return to the channel configuration menu, and adjust the offset by increasing or decreasing the value.

13. Once the offset has been zeroed, verify the calibration by applying known loads on the sensor throughout the load range, observing and verifying the measurement in engineering units.
6.3.2 EXAMPLE: Manufacturer Calibration

**NODE:** V-Link®-LXRS®, 16 bit (65536 A/D values)

**CHANNEL TYPE:** differential analog input, 0 to 3 V dc input range

**SENSOR TYPE:** pressure transducer, voltage output, positive going

**SENSOR PARAMETERS:**

From the manufacturer calibration sheet included with the sensor;

- sensor range: 0-250 psi
- sensor zero load output: 0.0032 V dc
- sensor full scale output (FSO) with 10V excitation: 86.07mV

From the application parameters;

- sensor excitation in application: 3V supply from the node

**DESIR ED OUTPUT:** engineering units (EU), psi

**CALCULATIONS:**

Because the sensor will be powered from the node with 3V, and the sensor manufacturer calibrated it a 10V, the manufacturer full scale output (FSO) value needs to be scaled to 3V.

\[(3V/10V) \times 86.07mV = 25.82mV\]

Select a gain and offset scale value appropriate for the sensor. Because the signal is positive going in this example application, the low offset scale will provide the largest range. With the low offset selected, the effective input range of the node is 75mV to 3V (2.25V) ([see Differential Input Gain and Offset on page 56](#)). Calculate the highest gain possible by dividing the actual input range by the sensor FSO.

\[2.25V/25.82mV = 87\]

The closest gain setting below optimal gain for a V-Link®-LXRS® is 75 (+/-20mV). Using a higher gain value would exceed the input voltage capacity of the node when the sensor is at higher pressures. This selection makes sense because the approximate input range designation for a gain of 75 is +/-20mV (a 40mV delta minus 10mV for the low offset), which is close to the FSO range of the sensor.
Multiply the sensor FSO by the gain setting to get the sensor voltage after amplification.

\[ 75 \times 25.82\text{mV} = 1.9365\text{V} \]

Scale the (gained) sensor input voltage/EU ratio to the node input voltage/EU ratio to determine the equivalent node FSO value (x).

\[ \frac{1.9365\text{V}}{250\text{psi}} = \frac{3\text{V}}{x} \]
\[ (250\text{psi} \times 3\text{V}) / 1.9365\text{V} = x = 387.3\text{psi} \]

The node converts voltage inputs to A/D values. For a 16-bit node, there are 65536 A/D values over the 3V input range. Divide the node EU FSO by the A/D value to get the ratio, or slope, of EU to A/D value.

\[ 387.3\text{ psi} / 65536\text{ bits} = 0.00591 = \text{slope} \]

Once the slope is entered, the sensor offset value can be measured in a data sampling session, such as streaming. Sample the sensor channel with no load applied, and read the EU value. Enter this as a negative value for the offset in order to have it subtracted from readings.
6.3.3 EXAMPLE: Internal Shunt Calibration

**NODE:** V-Link® -LXRS®, 16 bit (65536 A/D values)

**CHANNEL TYPE:** differential analog input, 0 to 3 V dc input range

**SENSOR TYPE:** strain gauge, Wheatstone Bridge, full bridge configuration

**SENSOR PARAMETERS:** application voltage range: +/-2mV

This is the expected output voltage of the strain gauge based on the range of strain being measured in the application and the sensitivity of the gauge (volts/strain).

**DESIRED OUTPUT:** engineering units, microstrain

**PROCEDURE:**

1. Open Node Commander®, and establish communication with the gateway and node.  
   *(See System Operational Overview on page 11.)*

2. Right-click on the node name, and select Configure > Configure Node.

3. Select the check-box for Channel 1, which is where the strain gauge is connected, and then select the Configure button.

![Figure 47 - Node Configuration Menu](image)
4. Use the following settings;

a. **Conversion Coefficients, Class**: Strain

b. **Conversion Coefficients, Units**: uStrain

c. **PGA Settings, Hardware Gain**: 104

d. **PGA Setting**: Midscale (for positive and negative going signals)

5. Select the Auto Balance button to tare the no-load value of the strain gauge. Observe the value returned for the Auto Balance value.

---

**Figure 48 - Channel Settings**
6. Select the Strain Wizard.

7. Select the appropriate Bridge Type and click Next.

8. Select Use the Strain Measurement Wizard and click Next.

9. Set the following parameters:
   
   a. **Number of Active Gauges**: number of a strain elements connected (for example: 4 for a full-bridge, and 2 for a half-bridge)
   
   b. **Gauge Factor**: ratio of mechanical strain to electrical output (a gauge specification).
   
   c. **Gauge Resistance**: Enter the strain gauge ohm value (a gauge specification).
   
   d. **Shunt Resistance**: 499000 ohms

   ![Figure 49 - Strain Wizard Settings](image)

**NOTE**

Touching sensors and test boards or charging the node battery while acquiring data may induce noise on sensitive sensor signals and is not recommended.
10. Select Calibrate.

11. Verify the calibration looks as shown in Figure 50 - Strain Gauge Calibration. The green line represents the output of the strain gauge. With no load applied it should sit near the Auto Balance baseline value, represented by the red dashed line. During calibration, a shunt resistance (selected on the Parameters page) is applied across the strain bridge, shown by the square pulse on the output. The Offset value, shown with the dashed blue line, is the average output value of the pulse and should sit across the top of the pulse. If the gauge has not had time to equilibrate before sampling, or if varying environmental factors exist, spikes in the gauge output may occur and affect the Baseline and Offset values. If this occurs, the Offset and Baseline values can be adjusted to clip the spikes in the output values. Adjust them as needed, and select Accept when completed.

![Shunt Calibration Graph](image)

**Figure 50 - Strain Gauge Calibration**
12. Select Finish to end the Strain Wizard. Note the slope and offset values have been calculated automatically.

![Completed Strain Wizard](image)

**Figure 51 - Completed Strain Wizard**

13. Select OK to exit the Channel Configuration window.

14. In the Node Configuration window, select Apply to write the configuration and calibration values to the node.

15. Select OK to exit.

![Apply Node Settings](image)

**Figure 52 - Apply Node Settings**
7. Powering the Node

WARNING

Apply only the input voltage range specified for the node in the polarity indicated. Failure to do so could result in personal injury and permanent damage to the node (see Safety Information on page 104).

The node can be powered with either the internal battery or an external source. These sources cannot be used simultaneously; there is switch on the node to select which source to use. When the node is manufactured, the switch is set to operate using the internal battery.

External battery holders and a ruggedized outdoor housing that accommodates two D cell batteries are also available for the SG-Link®-LXRS® and can be used to extend battery operating capacity and duration. For more information see Node Accessories on page 96.
7.1 Selecting the Power Source

The SG-Link®-LXRS® contains an internal, rechargeable Lithium Polymer (Li-Po) battery. For important precautions see Safety Information on page 104.

There is user-accessible switch to select the power source.

1. Verify the node power switch is in the OFF position and no external power is applied.
2. Use a small flat-head screwdriver to push the recessed switch fully to the desired position, as indicated in Figure 53 - Power Source Selection. The figure shows the node configured for an internal power source.

Figure 53 - Power Source Selection
7.2 Using the Internal Node Battery

The SG-Link®-LXRS® contains an internal, rechargeable Lithium Polymer (Li-Po) battery. For important precautions see Safety Information on page 104.

When the internal node switch is set for internal power, the node is powered by a rechargeable, 250 mAh lithium polymer battery. This battery is not user-serviceable.

Node battery life is highly dependent on the type of sensor connected, as well as operational parameters such as sample mode and rate. Higher sample rates equate to decreased battery life. The following graph shows an example approximation of the battery life for a SG-Link®-LXRS® with different strain gauge sensor configurations over a range of sample rates operating in Synchronized Sampling mode. For additional SG-Link®-LXRS® power specifications see Power Profile on page 102.
7.3 Charging the Node Battery

Use only the power supply specified for the node to charge the battery. Using a power supply above the rated voltage could cause personal injury and permanent damage to the node. For important safety considerations see Safety Information on page 104.

**NOTE**

Touching sensors and test boards or charging the node battery while acquiring data may induce noise on sensitive sensor signals and is not recommended.

1. Turn the node power switch off, and plug the node power supply into the node and then into a 120/240VAC, 50/60Hz AC power source. Use only the power supply specified for the node. Use the supplied power plug adapters, as needed.

2. Monitor the status of the charge indicators. For indicator meaning see Device Status Indicators on page 81. Continue charging until the indicator turns green to indicate a completed charge. Charging takes approximately 6-8 hours from a full depletion.

![Figure 54 - Node Charging](image)
7.4 Connecting an External Power Supply

Apply only the input voltage range specified for the node in the polarity indicated. Failure to do so could result in personal injury and permanent damage to the node (see Safety Information on page 104).

When the internal node switch is set for external power, the node may be directly powered by the power supply specified for charging the node (or another regulated AC to DC power supply with the appropriate output parameters, see Operating Specifications on page 100). It can also be powered by an external battery or other regulated DC supply. The supply must deliver a stable voltage between 3.2 and 9.0 V dc and be capable of sourcing at least 100 mA. Power supplies over 9 V dc, such as vehicle batteries, can be used by installing a step-down regulator (for SG-Link®-LXRS® power use specifications see Power Profile on page 102). External battery holders and ruggedized outdoor housings that accommodate D cell batteries are available for the SG-Link®-LXRS® (see Node Accessories on page 96).

External power is applied through either the power supply jack, or the terminal block connectors. Do not connect both. Observe connection polarities, or the node may be damaged.

Figure 55 - External Power Connections
8. Troubleshooting

8.1 Troubleshooting Guide

1. POWER gateway or node does not turn on, or node does not charge
   1.1 node or gateway power is off
   1.2 external power is off or miswired
   1.3 wrong power supply
   1.4 node internal source select is incorrect
   1.5 node battery is dead
   1.6 node battery fault
   1.7 sensors are drawing too much current
   1.8 node or gateway is damaged

2. COMMUNICATION no communication to the gateway or node
   2.1 node or gateway has no power
   2.2 gateway has no com with computer
   2.3 node cannot be configured
   2.4 node is out of range
   2.5 node is not in normal boot mode
   2.6 node is sampling
   2.7 node is sleeping
   2.8 gateway or node is damaged

3. DATA ACQUISITION sensor data is missing or incorrect
   3.1 no com to node or gateway
   3.2 sampling settings are incorrect
   3.3 sampling has not started
   3.4 sensor is not connected correctly
   3.5 sensor channel not configured correctly
   3.6 sensor calibration is invalid

Table 6 - Device Status Indicators
8.3 Using the Node Tester Board

The node tester board is used to verify node and network functions before sensors are connected, or for diagnostic purposes. The node tester board provides a fixed load so system functions can be verified including basic operations not related to the sensor, such as communication and sampling. A fixed load is applied to the differential input by pressing the load button. The SG-Link®-LXRS® also features a photo cell that can be used to apply a variable load the single-ended channel. Adjust the load by changing the amount of light on the face of the photo cell.

There are various impedance value node tester boards available, depending on the node it is being used with. See Parts and Configurations on page 95 for configuration options and part numbers. Each is configurable to emulate full, half and quarter bridge strain gauges. Table 7 - Tester Board Configuration describes the strain gauge load settings available. This setting must match the type of node channel that is being tested. For example if the node is a quarter-bridge node, the setting on the tester board must be the same. The configuration chart is also printed on the underside of the board.

NOTE
The switches may come with a protective film covering them. Simply peel the film off to access the switches.

Table 7 - Tester Board Configuration
The following steps describe an example of how to use the tester board to sequence through the primary functions of the node and the wireless system. If the results indicated in the final steps are achieved, the system is fully operational for measuring a full bridge strain gauge. Other scenarios can be tested as needed.

1. Set the jumpers for Full Bridge operation, using a small flat head screw driver to fully push the switch into the desired position.

2. Verify the node is powered off and unplugged.

3. Plug the node tester board into the node in the orientation shown, and screw the board in place.

![Figure 56 - Node Tester Board Installation](image)

4. If not already completed, set up the Wireless Sensor Network equipment and install the Node Commander® software. See System Operational Overview on page 11.

5. Launch the Node Commander® software, and establish communications with the gateway and node.
6. Enter the node channel configuration menu by right-clicking on the node heading in Node Commander® and selecting Configure > Configure Node, and then the Channels tab.

![Node Configuration Menu](image)

**Figure 57 - Node Configuration Menu**

7. Select the check box for Channel 1, which is where the Node Tester Board is installed, and then select Configure.

![Node Channel Configuration](image)

**Figure 58 - Node Channel Configuration**
8. Use the following settings for the node tester board.

a. **Conversion Coefficients, Units:** uStrain

b. **Conversion Coefficients, Class:** Strain

c. **PGA Settings, Input Range:** +/-2.5mV

d. **PGA Setting:** Midscale

9. Select the Auto Balance button to tare the no load value of the tester board.

![Figure 59 - Channel Settings](image-url)
10. Select the Strain Wizard.

11. Select Full Bridge for the Bridge Type and click Next.

12. Select Use the Strain Measurement Wizard, and click Next.

13. Set the following for the Node Tester Board
   a. **Number of Active Gauges**: 4
   b. **Gauge Factor**: 2
   c. **Gauge Resistance**: Enter the node tester board ohm value.
   d. **Shunt Resistance**: 499000 ohms

![Strain Wizard Settings](image)

**Figure 60 - Strain Wizard Settings**

15. Verify the calibration looks as shown in Figure 61 - Strain Gauge Calibration. The green line represents the output of the strain gauge. With no load applied it should sit near the Auto Balance baseline value, as shown, and is represented by the red dashed line. During calibration, a shunt resistance (selecting on the Parameters page) is applied across the strain bridge, shown by the square pulse on the output. The Offset value, shown with the dashed blue line, is the average output value of the pulse and should sit across the top of the pulse. If the gauge has not had time to equilibrate before sampling, or varying environmental factors exist, spikes in the gauge output may occur and affect the Baseline and Offset values. If this occurs, the Offset and Baseline values can be adjusted to clip the spikes in the output values. Adjust them as needed, and select Accept when completed.

![Shunt Calibration Graph](image)

**Figure 61 - Strain Gauge Calibration**
16. Select Finish to end the Strain Wizard. Note that the slope and offset values have been calculated.

![Completed Strain Wizard Image]

Figure 62 - Completed Strain Wizard

17. Select OK to exit the channel Configuration window.

18. In the Node Configuration window, select the Streaming tab. Uncheck Continuous Streaming, and set the Time Duration to 15 seconds.

19. Select Apply to write configuration and calibration values to the node. Select OK to exit.

**NOTE**

Touching sensors and test boards or charging the node battery while acquiring data may induce noise on sensitive sensor signals and is not recommended.

**NOTE**

There are many sampling options available in the Node Commander® software. The following describes just one option, for illustrative purposes.
20. Right-click on the Node heading and then select Sample > Stream > Start.

21. As soon as Start is selected, the node will start collecting data for a duration of 15 seconds. During that time, press and release the load button on the node tester board to shunt the resistive load on and off. Verify the result is as shown in the figure below. The pulse value should equal tester board ohm value. Testing is complete.
8.4 Updating Node Firmware

Under the recommendation of LORD MicroStrain® Technical Support Engineers, nodes can be upgraded to the latest available firmware to take advantage of new features or correct operating issues. Node Commander® version 2.7.0 or greater can be used to update any mXRS® or LXRS® node or gateway firmware to the most current version. Updates are found on the LORD MicroStrain® website. See Technical Support on page 93 for contact and website information.

1. Download the LXRS® Firmware Upgrade file from the LORD MicroStrain® website.

2. Once downloaded, extract the contents of the .zip file into a folder on the computer. Verify there is a file with a .zhex extension.

3. Launch Node Commander®, and establish communication between the node and gateway as normal.

4. While holding F1 button on the keyboard, right-click the node name, and a drop-down menu will appear.

![Figure 65 - Update Node Firmware](image-url)
5. Release the F1 key.

6. Click Upgrade Firmware, and the Node Firmware Upgrade window will appear.

7. Click Browse, and navigate to the downloaded .zhex file.

8. Click Write, and the upgrade sequence will begin. When completed, "Upgrade Success" will appear in the Status column.

Figure 66 - Upgrade Firmware Window
8.5 Repair and Calibration

The SG-Link®-LXRS® has no components which require factory calibration and certification.

**General Instructions**

In order to return any LORD MicroStrain® product, you must contact LORD MicroStrain® Sales or Technical Support to obtain a Return Merchandise Authorization number (RMA). All returned merchandise must be in the original packaging including manuals, accessories, cables, etc. with the RMA number clearly printed on the outside of the package. Removable batteries should be removed and packaged in separate protective wrapping. Please provide the LORD MicroStrain® model number and serial number as well as your name, organization, shipping address, telephone number, and email. Normal turn-around for RMA items is seven days from receipt of item by LORD MicroStrain®.

**Warranty Repairs**

LORD MicroStrain® warrants its products to be free from defective material and workmanship for a period of one (1) year from the original date of purchase. LORD MicroStrain® will repair or replace, at its discretion, a defective product if returned to LORD MicroStrain® within the warranty period. This warranty does not extend to any LORD MicroStrain® products which have been subject to misuse, alteration, neglect, accident, incorrect wiring, mis-programming, or use in violation of operating instructions furnished by us. It also does not extend to any units altered or repaired for warranty defect by anyone other than LORD MicroStrain®.

**Non-Warranty Repairs**

All non-warranty repairs/replacements include a minimum charge. If the repair/replacement charge exceeds the minimum, LORD MicroStrain® will contact the customer for approval to proceed beyond the minimum with the repair/replacement.
8.6 Technical Support

There are many resources for product support found on the LORD MicroStrain® website, including technical notes, FAQs, and product manuals.

http://www.microstrain.com/support_overview.aspx

For further assistance our technical support engineers are available to help with technical and applications questions.

Technical Support

sensing_support@LORD.com

Phone: 802-862-6629
Fax: 802-863-4093

SKYPE: microstrain.wireless.support

Live Chat is available from the website during business hours:
9:00 AM to 5:00 PM (Eastern Time US & Canada)
9. Maintenance

There are no user-serviceable parts on the SG-Link®-LXRS®. For device service and repair contact LORD MicroStrain® Technical Support (see Technical Support on page 93).
10. Parts and Configurations

10.1 Standard Nodes

For the most current product information, custom, and OEM options not listed below, refer to the LORD MicroStrain® website or contact the LORD MicroStrain® Sales Department.

11.3 Power Profile

Node power use is highly dependent on the number and type of sensors connected and operational parameters such as sample mode and rate. More active channels and higher sample rates equate to increased power use. Below is an example approximation of the power use of a SG-Link®-LXRS® with different strain gauge sensor configurations over a range of sample rates operating in Synchronized Sampling mode. This chart can be used to approximate external node power source requirements. For SG-Link®-LXRS® internal battery life specifications see Using the Internal Node Battery on page 73.

![SG-Link® - LXRS® Example Power Profile](image)

Figure 67 - Example SG-Link®-LXRS® Power Profile
11.4 Radio Specifications

The SG-Link®-LXRS® Wireless Sensor Node employs a 2.4GHz IEEE 802.15.4 compliant radio transceiver for wireless communication. The radio is a direct-sequence spread spectrum radio and can be configured to operate on 14 separate frequencies ranging from 2.405 GHz to 2.470 GHz. Following the 802.15.4 standard, these frequencies are aliased as channel 11 through channel 24. For all newly manufactured nodes, the default setting is equivalent to 2.425 GHz (channel 15).

For standard models, radiated transmit power is programmable from 0 dBm (1 mW) to 16 dBm (39 mW). A low transmit power option is available (for use in Europe and elsewhere) and is limited to 10 dBm (10 mW).

The radio complies with ETSI EN 300 328, EN 300 440 Class 2 (Europe), FCC CFR-47 Part 15 (USA), and ARIB STD-T66 (Japan) regulations. The radio is license-free worldwide. Using antennas and transmission equipment other than what is provided may void FCC compliance.

NOTE

- The gateway can automatically manage nodes operating on different frequencies by using the Node Discovery feature in Node Commander®. In this routine, the gateway listens for node broadcasts on the frequency channel to which it is set. If the node is in normal boot-up mode, it will provide the broadcast when it is initially powered on and broadcast on all channels. As long as the node is powered on after activating the Node Discovery feature, the gateway will link to it and remember the channel setting for future node queries.

- Manually matching the node and gateway frequency channels is required in some applications. For example, when sending broadcast messages from the gateway to multiple nodes (including the synchronized sampling beacon) all nodes must be on the same channel as the gateway in order to receive the broadcast. Assigning channels is also a good idea when multiple gateways are attached to one host computer or when other wireless equipment is nearby and frequency or transmission interference may occur.
12. Safety Information

This section provides a summary of general safety precautions that must be understood and applied during operation and maintenance of components in the LORD MicroStrain® Wireless Sensor Network. Throughout the manual, ANSI Z535 standard safety symbols are used to indicate a process or component that requires cautionary measures.

12.1 Battery Hazards

The SG-Link®-LXRS® contains an internal, rechargeable Lithium Polymer battery. Lithium Polymer batteries are a fire and explosion hazard. Do not store or operate the node at temperatures above 212°F (100°C). Do not disassemble, short circuit, crush, puncture, or otherwise misuse the battery.

When recharging the node internal battery, use only the power supply specified for node charging, and follow the instructions. See Charging the Node Battery on page 74. Applying a voltage above the input range may result in dangerous battery conditions and cause permanent damage to the node.

Lithium Polymer batteries contain toxic chemicals that are harmful to humans and the environment. Disposal is subject to federal and local laws. Do not discard the battery or the node in the trash. Follow proper battery disposal protocol, or contact LORD MicroStrain® Technical Support for information on extracting the battery or returning the product for proper recycling and disposal.
12.2 User Configurable Power Settings

The SG-Link®-LXRS® Wireless Sensor Node can be powered by either the internal battery or an external source. There is user-accessible switch to select the source. The default setting for this switch is for internal battery operation and charging. See Selecting the Power Source on page 72.

**CAUTION NOTICE**

Connecting an external power source when the node is set to internal power could result in injury or permanent node damage. For details on how to adjust the switch setting see Connecting an External Power Supply on page 75.

- If the node is set to use an external source, and the charging power supply is plugged in, it will power the node from the power supply and not charge the battery. It will continue to use the internal battery.

- If the node is set to internal, and an external power supply other than the one used for charging is plugged in, several things could happen. If it is a power supply that is in the operating range of the charging circuit, it may charge the battery. If it is below the range of the charging circuit, nothing will happen. If the applied voltage is above the range of the charging circuit, damage to the node will likely occur and personal injury may result.

- When under battery operation there is a limit to how much current the node can provide to sensors. If the node is in an over-current condition it will shut off until the cause is removed. Using an external power source for the node or sensor can mitigate this issue.
12.3 Power Supply

The SG-Link®-LXRS® Wireless Sensor Node can be powered by an external source.

![WARNING CAUTION NOTICE]

Apply only the input voltage range specified for the SG-Link®-LXRS®. Connect to a power source that is near the device, is accessible, and adheres to all national wiring standards. Compliance with wiring standards is assumed in the installation of the power source and includes protection against excessive currents, short circuits, and ground faults. Failure to do so could result in personal injury and permanent damage to the device. For details on how to connect the power supply see Connecting an External Power Supply on page 75.

12.4 ESD Sensitivity

The SG-Link®-LXRS® is susceptible to damage and/or disruption of normal operation from Electrostatic Discharge (ESD), particularly during data acquisition.

![CAUTION NOTICE]

ESD damage can occur when the device is touched, especially at the device interfaces such as the antenna and connectors. Use proper grounding techniques when handling. If an ESD event occurs and operation has been interrupted, reset the device by cycling power to it and/or restarting the operational mode in the system software.
13. References

13.1 Reference Information

Many references are available on the LORD MicroStrain® website including product user manuals, technical notes, and quick start guides. These documents are continuously updated, and new applications are added. They may provide more accurate information than printed or file copies.

Table 10 - Related Documents
13.2 Glossary

These terms are in common use throughout the manual:

**A/D Value**: the digital representation of the analog voltages in an analog to digital (A/D) conversion. The accuracy of the conversion is dependent on the resolution of the system electronics; higher resolution produces a more accurate conversion. Also referred to as 'bits'.

**ASTM**: The Association of Standards and Testing is a nationally-accepted organization for the testing and calibration of technological devices.

**Base Station**: The base station is the transceiver that attaches to the host computer and provides communication between the software and the node(s). It is also referred to as a “gateway”.

**Bits**: the digital equivalent of voltage on the node. See 'A/D Value'.

**Burst Sampling**: a mode of operation in synchronized sampling that takes momentary high sample rate readings with configurable time durations and intervals

**Calibration**: to standardize a measurement by determining the deviation standard and applying a correction (or calibration) factor

**Configuration**: a general term applied to the node indicating how it is set up for data acquisition. It includes settings such as sampling mode and rate, number of active channels, channel measurement settings, offsets, hardware gain, and calibration values.

**Coordinated Universal Time (UTC)**: the primary time standard for world clocks and time. It is similar to Greenwich Mean Time (GMT).

**Cycle Power**: a command transmitted to the node to re-boot it, either through a hardware or software switch

**Data Acquisition**: the process of collecting data from sensors and other devices

**Data Logging**: the process of saving acquired data to the system memory, either locally on the node or remotely on the host computer

**DHCP (network)**: Dynamic Host Configuration Protocol is the standardized networking protocol used on Internet Protocol (IP) networks, which automatically configures devices that are attached to it by assigning and configuring the device IP address.
**Differential (signal):** is a method of transmitting electrical signals in which they are paired together as a differential pair and measured with reference to each other only. This method makes the pair less susceptible to electrical noise.

**EMI:** Electromagnetic Interference is an inductive or radiated disturbance that can create signal degradation on electrical signals, including loss of data.

**ESD:** Electrostatic Discharge is the sudden flow of electricity that can occur between two charged objects of different potential that come in contact or in close proximity of each other. Static electricity is a common source of ESD.

**Firmware:** the code that is programmed onto a microcontroller or similar device in an embedded system that includes device operation commands, conditions, memory allocation, and many other tasks

**Gateway:** The gateway is a transceiver that attaches to the host computer and provides communication between the software and the node(s). It is also known as a “base station”.

**Host (computer):** The host computer is the computer that orchestrates command and control of attached devices or networks.

**LED:** Light Emitting Diode is an indicator light that is used in electronic equipment.

**LOS (Line of Sight):** is used in radio communications to describe the ideal condition between transmitting and receiving antennas in a radio network. As stated, it means they are in view of each other with no obstructions.

**LXRS®:** Lossless Extended Range Synchronized is the LORD MicroStrain® data communications protocol used in the wireless sensor network.

**NIST:** The National Institute of Standards and Testing is a nationally-accepted organization for testing and calibration of technological devices.

**Node:** The node is the wireless transceiver that the sensor(s) is connected to, providing communication with the gateway. The G-Link®-LXRS®, V-Link®-LXRS®, and SG-Link®-LXRS® are all nodes manufactured by LORD MicroStrain®.

**Node Tester board:** The Node Tester board is a device designed by LORD MicroStrain® that can be plugged into nodes to test their functionality.
Offset: When describing a mathematically-linear relationship, the offset is the value where the line that represents the relationship in a graph crosses the y-axis. The equation of a straight line is: \( y = mx+b \), where \( x \) is the x-axis coordinate, \( y \) is the y-axis coordinate, \( m \) is the slope and \( b \) is the offset.

Oversampling: In signal processing, oversampling is a technique used to achieve increased signal resolution and better noise immunity by recording readings at a higher frequency than the output of the device being measured. In analog-to-digital conversion, the higher the oversampling rate, the better the analog signal is recreated.

Packet: unit of sampled data

Ping: A byte is transmitted by the gateway to the node, and the node responds by echoing the byte, indicating communication exists between the node and gateway.

PGA: A Programmable Gain Amplifier is an electronic device used to amplify small electrical signals.

Range Test: a continuous string of pings used to validate communication between the gateway and the node over distance and obstruction

Read/Write EEPROM: commands transmitted to the node to read or write parameters stored in the node’s operating system

Real Time Clock (RTC): a computer clock that keeps track of the current time

Resolution: in digital systems, the resolution is the number of bits or values available to represent analog values or information. For example, a 12-bit system has 4,096 bits of resolution and a 16-bit system has 65,536 bits.

RFI: Radio Frequency Interference is a disturbance in an electrical circuit due to electromagnetic induction or radiation.

RSSI: Received Signal Strength Indication is a measurement of the transmission power in a radio signal. The units are decibels with reference to 1 milliWatt (dBm).

RS232: a serial data communications protocol

Sensor: a device that physically or chemically reacts to environmental forces and conditions and produces a predictable electrical signal as a result

Sleep: a command transmitted to the node to put it into sleep configuration
Sampling: the process of taking measurements from a sensor or device

Sampling Mode: the type of sampling that is being utilized, such as event-triggered, continuous, or periodic. The nodes have several sampling modes that employ these types of sampling.

Sampling Rate: the frequency of sampling

Single Ended: electrical signals that are measured with reference to a system ground

Slope: When describing a mathematically linear relationship, the slope is the steepness of the line that represents that relationship on a graph. The equation of a straight line is: \( y = mx + b \), where \( x \) is the x-axis coordinate, \( y \) is the y-axis coordinate, \( m \) is the slope, and \( b \) is the offset.

Streaming: Streaming is a sampling mode in which all active channels (and the sensors attached to them) are measured, and the data acquired is transmitted to the gateway and software. The data is not written to non-volatile memory during streaming. Streaming can either be finite (have a user defined start and end time) or continuous (continue until the power is cycled on the node).

Synchronized Sampling: a sampling mode that automatically coordinates all incoming node data to a particular gateway. This mode is designed to ensure data arrival and sequence.

Transmission rate: the number of data packets per transmission window in seconds. Depending on the sampling mode and settings it will be between 1 and 64 packets/second.

Transmission window: the time allowed for one data transmission at the automatically determined transmission rate

USB: Universal Serial Bus, a serial data communications protocol

Wheatstone Bridge: an electrical circuit used to measure unknown electrical resistances

WSN: Wireless Sensor Network describes a distribution of sensors and data acquisition equipment that autonomously monitors environmental characteristics, such as temperature, pressure, and strain.
